Selina Class 10 ICSE Solutions Biology :

Chapter 5- Photosynthesis: Provider of Food for All

Class 10: Biology Chapter 5 solutions. Complete Class 10 Biology Chapter 5 Notes.

Selina Class 10 ICSE Solutions Biology : Chapter 5- Photosynthesis: Provider of Food for All

Selina 10th Biology Chapter 5, Class 10 Biology Chapter 5 solutions

Exercise 1

Solution A.1.

b) glucose formed in photosynthesis soon gets converted into starch

Solution A.2.

b) twelve

Solution A.3.

b) humidity

Solution A.4.

c) trapping light energy

Solution A.5.

a) continue to live, but will not be able to store food

Solution A.6.

<https://www.indcareer.com/schools/selina-class-10-icse-solutions-biology-chapter-5-photosynthesis-provider-of-food-for-all/>

a) Carbon dioxide is reduced and water is oxidised

Solution A.7.

c) activate chlorophyll

Solution A.8.

d) ensure that the leaves are free from starch

Solution A.9.

a) CO₂

Solution B.1.

(a) Producers / Autotrophs

(b) Chloroplasts

(c) ATP (Adenosine triphosphate)

(d) Glucose

(e) Green plants

(f) Carbon dioxide dissolved in water

(g) Stroma

(h) Phloem

Solution C.1.

(a)

Respiration

The gas released during respiration is carbon dioxide.

Photosynthesis

The gas released during photosynthesis is oxygen.

<https://www.indcareer.com/schools/selina-class-10-icse-solutions-biology-chapter-5-photosynthesis-provider-of-food-for-all/>

(b)

Light Reaction

Hydrogen and oxygen are produced here, along with release of electrons, which converts ADP into ATP.

Dark Reaction

Glucose is the main product formed during dark reaction.

(c)

Producers

Producers show autotrophic mode of nutrition i.e. they are able to produce their own food from basic raw materials.

For example: green plants

Consumers

Consumers show heterotrophic mode of nutrition i.e. they depend directly or indirectly on the producers for their food.

For example: Animals

(d)

Grass

Green grass being a producer is capable of producing its own food by photosynthesis.

Grasshopper

Grasshopper is a primary consumer (herbivore) and directly feeds on producers like grass.

(e)

Chlorophyll

Chloroplast

Chlorophyll is the green pigment present in cell organelles called chloroplasts.

Chloroplasts are cell organelles, situated in the cytoplasm of plant cells. They are present mainly in the mesophyll cells and in the guard cells of stomata.

Solution C.2.

(a) False

Correct Statement: Dark reaction of photosynthesis is independent of light and occurs simultaneously with light reaction.

(b) True

(c) False

Correct Statement: Starch produced in a leaf is stored temporarily in the leaf until the process of photosynthesis. At night it is converted back into soluble sugar and translocated to different part of the body either for the utilization or for the storage.

(d) True

(e) False

Correct Statement: Green plants are producers.

(f) False

Correct Statement: Respiration results in loss of dry weight of the plants.

(g) False

Correct Statement: Photosynthesis stops at a temperature of above 40°C.

(h) True

(i) True

(j) True

Solution C.3.

<https://www.indcareer.com/schools/selina-class-10-icse-solutions-biology-chapter-5-photosynthesis-provider-of-food-for-all/>

- (a) grana
- (b) iodine solution
- (c) chloroplast
- (d) Calvin cycle
- (e) Sucrose

Solution C.4.

- (a) False

Photosynthesis increases with the light intensity up to a certain limit only and then it gets stabilized.

- (b) False

The atmospheric temperature is an important external factor affecting photosynthesis. The rate of photosynthesis increases up to the temperature 35°C after which the rate falls and the photosynthesis stops after 40°C.

- (c) False

Ice cold water will hamper the process of photosynthesis in the immersed leaf, even if there is sufficient sunshine because the temperature is an important factor for the rate of photosynthesis.

- (d) False

For destarching, the potted plant can kept in a dark room for 24-48 hours.

- (e) False

There is no start point or end point in the carbon cycle, the carbon is constantly circulated between the atmosphere and the living organisms.

- (f) False

If a plant is kept in bright light all the 24 hours for a few days, the dark reaction (biosynthetic phase) will continue to occur because the dark reaction is independent of light and it occurs simultaneously with the light dependent reaction.

<https://www.indcareer.com/schools/selina-class-10-icse-solutions-biology-chapter-5-photosynthesis-provider-of-food-for-all/>

(g) True

Solution C.5.

Photons, grana, water molecules, hydrogen and hydroxyl ions, oxygen

Solution C.6.

Photosynthesis	Respiration
Carbon dioxide is used up and oxygen is released.	Oxygen is used up and carbon dioxide is released.
Photosynthesis occurs in plants and some bacteria.	Respiration occurs in all living organisms.
Photosynthesis results in gain of dry weight of the plants.	Respiration results in loss of dry weight of the plants.
Glucose is produced which is utilized by the plants.	Glucose is broken down to obtain energy.
The raw materials for the photosynthesis are water, carbon dioxide and sunlight.	The raw material for respiration is glucose.

(Any 4)

Solution C.7.

Oxygen is released during photosynthesis. Some of this oxygen may be used in respiration in the leaf cells, but the major portion of it is not required and it diffuses out into the atmosphere through the stomata. However, in a sense, even this oxygen is not a waste because all organisms require it for their existence including the plants.

Solution C.8.

The presence of starch is regarded as evidence of photosynthesis. Hence before starting an experiment on photosynthesis, the plant should be placed in the dark for 24-48 hours to destarch the leaves. During this period, all the starch from the leaves will be sent to the storage

<https://www.indcareer.com/schools/selina-class-10-icse-solutions-biology-chapter-5-photosynthesis-provider-of-food-for-all/>

organs and the leaves will not show the presence of starch. So the various experiments on photosynthesis can be carried out effectively.

Solution C.9.

Destarching means removal of starch. Destarching is carried out so that all the starch from the leaves will be sent to the storage organs. Hence all the leaves will not show the presence of starch and photosynthesis can be studied. Destarching ensures that any starch present after the experiment has been formed under experimental conditions.

Solution C.10.

If a green plant is kept in bright light, it tends to use up all the CO_2 produced during respiration, for photosynthesis. Thus, the release of CO_2 cannot be demonstrated. Hence, it is difficult to demonstrate respiration as these two processes occur simultaneously.

Solution C.11.

The chloroplasts are concentrated in the upper layers of the leaf which helps cells to trap the sunlight quickly. Also the epidermis is covered by a waxy, waterproof layer of cuticle. This layer is thicker on the upper surface than the lower one. Hence most leaves have the upper surface more green and shiny than the lower one.

Solution C.12.

- Place hydrilla plant (a water plant) in a beaker containing pond water and cover it by a short-stemmed funnel. (Make sure the level of water in the beaker is above the level of the stem of the funnel)
- Invert a test tube full of water over the stem of the funnel.
- Place the set up in the sun light for a few hours.

Observation:

Bubbles appear in the stem which rise and are collected in the test tube. When sufficient gas gets collected, a glowing splinter will be introduced in the test tube, which will burst into flames.

Inference:

The splinter glows due the presence of oxygen in the test tube which proves that the gas collected in the test is released by hydrilla during photosynthesis.

<https://www.indcareer.com/schools/selina-class-10-icse-solutions-biology-chapter-5-photosynthesis-provider-of-food-for-all/>

Solution C.13.

(i) Light Reaction:

The light reaction occurs in two main steps:

1. Activation of chlorophyll – On exposure to light energy, chlorophyll becomes activated by absorbing photons.
2. Splitting of water – The absorbed energy is used in splitting the water molecule into hydrogen and oxygen, releasing energy. This reaction is known as photolysis of water.

The fate of H^+ , e^- and (O) component are as follows:

The hydrogen ions (H^+) obtained from above are picked up by a compound NADP (Nicotinamide adenine dinucleotide phosphate) to form NADPH.

The oxygen (O) component is given out as molecular oxygen (O_2).

The electrons (e^-) are used in converting ADP into energy rich ATP by adding one inorganic phosphate group P_i .

<https://www.indcareer.com/schools/selina-class-10-icse-solutions-biology-chapter-5-photosynthesis-provider-of-food-for-all/>

This process is called photophosphorylation.

(ii) **Dark reaction:** The reactions in this phase does not require light energy and occur simultaneously with the light reaction. The time gap between the light and dark reaction is less than one thousandth of a second. In the dark reaction, ATP and NADPH molecules (produced during light reaction) are used to produce glucose ($\text{C}_6\text{H}_{12}\text{O}_6$) from carbon dioxide. Fixation and reduction of carbon dioxide occurs in the stroma of the chloroplast through a series of reactions. The glucose produced is either immediately used up by the cells or stored in the form of starch.

Solution C.14.

Complete the following food chains by writing the names of appropriate organisms in the blanks:

(i) Grass → Rabbit. → Snake → Hawk

(ii) Grass/Corn → Mouse → Snake → Peacock

Solution C.15.

Non-green plants such as fungi and bacteria obtain their nourishment from decaying organic matter in their environment. This matter comes from dead animals and plants. Fungi and bacteria break down the organic matter to obtain the nourishment and they release carbon dioxide back in the atmosphere.

Solution C.16.

<https://www.indcareer.com/schools/selina-class-10-icse-solutions-biology-chapter-5-photosynthesis-provider-of-food-for-all/>

Chlorophyll is the foundation site for the photosynthesis in green plants. The initiation of photosynthesis takes place when the chlorophyll molecule traps the light energy. The light energy is then converted into chemical energy in the form of glucose using carbon dioxide (CO_2) from the atmosphere, and water (H_2O) from the soil. All other organisms, directly or indirectly depend on this food for their survival. The starting point of any food chain is always a plant. If green plants were to suddenly disappear, then so would virtually all life on Earth. Thus, we can say that all life owes its existence to chlorophyll.

Solution C.17.

To test the leaf for starch, the leaf is boiled in water **to kill the cells**. It is next boiled in methylated spirit to **remove chlorophyll**. The leaf is placed in warm water to soften it. It is then placed in a dish and **iodine** solution is added. The region, which contains starch, turns **blue-black** and the region, which does not contain starch, turns **brown**.

Solution D.1.

- a. The student wanted to show that sunlight is necessary for photosynthesis. / The role of sunlight in photosynthesis is being investigated.
- b. Yes. The other uncovered leave of the potted plant act as a control.
- c. Destarching ensures that any starch present after the experiment has been formed under experimental conditions. Therefore, the plant was kept in the dark before the experiment.
- d.
 - The student dipped the leaf in boiling water for a minute to kill the cells.
 - Then he boiled the leaf in alcohol/methylated spirit over a water bath to remove chlorophyll. The leaf becomes hard and brittle.
 - He then places the leaf in hot water to soften it.
 - Next the student spreads the leaf in a dish and pours iodine solution on it. The presence of starch is indicated by a blue-black colour.
 - The uncovered portion (exposed to sunlight) turned blue-black colour and the covered portion showed brown colour. The difference in the colours of covered and uncovered part of leaves indicates the importance of sunlight in photosynthesis.

Solution D.2.

(a) Guard cells: They regulate the opening and closing of stomata and thus regulate the entry of carbon dioxide through the stomata.

<https://www.indcareer.com/schools/selina-class-10-icse-solutions-biology-chapter-5-photosynthesis-provider-of-food-for-all/>

(b) Cuticle: Cuticle is transparent and water proof due to which light can penetrate this later easily.

(c) Mesophyll cells: Mesophyll cells are the main sites for photosynthesis. Chloroplasts are mainly contained in the mesophyll cells. When sunlight falls on the leaf, the light energy is trapped by the chlorophyll of the upper layers of mesophyll, especially the palisade cells.

(d) Xylem Tissue in the Leaf Veins: Water is essential for photosynthesis to occur. Water is taken up by the roots from the soil, sent up through the stem and finally brought to the leaves (site of photosynthesis) through the xylem tissue. The water is then distributed in the mesophyll tissue.

(e) Phloem Tissue in the Leaf Veins: The prepared food is transported from leaves to all parts of the plant by the phloem tissue. The glucose is converted into insoluble starch and later into soluble sugar i.e. sucrose, which is transported in solution through the phloem in the veins of the leaf and down through the phloem of the stem.

(f) Stoma: The main function of stoma is to let in carbon dioxide from the atmosphere for photosynthesis. Also most of the oxygen produced during photosynthesis diffuses out into the atmosphere through the stomata.

Solution D.3.

a.

1. Sunlight
2. Oxygen
3. Glucose
4. Xylem

b. A – Transpiration

B – Translocation

Solution D.4.

a. Food chain

b. Hawk, eagle

c. Photosynthesis

<https://www.indcareer.com/schools/selina-class-10-icse-solutions-biology-chapter-5-photosynthesis-provider-of-food-for-all/>

d. Carbon

Solution D.5.

Test to determine the presence of starch in a leaf:

- Dip a leaf in boiling water for a minute to kill the cells.
- Boil the leaf in methylated spirit in a water bath to remove the chlorophyll, till the leaf turns pale blue and becomes hard and brittle.
- Now place the leaf in hot water to soften it.
- Place the leaf in a Petri dish and pour iodine solution over it.
- The appearance of a blue-black colour on the leaf is indicative of the presence of starch.
- The absence of starch is indicated by a brown colouration.

Solution D.6.

a. To demonstrate the importance of carbon dioxide in photosynthesis

b. No, the experiment will not work satisfactorily, as the beaker contains lime water and not potassium hydroxide to absorb CO_2 .

c. Place potassium hydroxide in the beaker instead of lime water

d. Before starting the experiment, it is necessary to destarch the leaves of the plant by keeping the plant in complete darkness for 48 hours. This is because if the plant is not destarched, then the experiment will give false results because starch stored previously may be detected in the leaf placed in the beaker even if no starch is produced during the experiment.

Solution D.7.

About About Selina Publishers ICSE

Selina Publishers has been serving the students since 1976 and is one of the quality ICSE school textbooks publication houses. Mathematics and Science books for classes 6-10 form the core of our business, apart from certain English and Hindi literature as well as a few primary books. All these books are based upon the syllabus published by the Council for the I.C.S.E. Examinations, New Delhi. The textbooks are composed by a panel of subject experts and vetted by teachers practising in ICSE schools all over the country. Continuous efforts are made in complying with the standards and ensuring lucidity and clarity in content, which makes them stand tall in the industry.
